## Surds and rationalising the denominator

## A LEVEL LINKS

Scheme of work: 1a. Algebraic expressions - basic algebraic manipulation, indices and surds

## Key points

- A surd is the square root of a number that is not a square number,
for example $\sqrt{2}, \sqrt{3}, \sqrt{5}$, etc.
- Surds can be used to give the exact value for an answer.
- $\sqrt{a b}=\sqrt{a} \times \sqrt{b}$
- $\sqrt{\frac{a}{b}}=\frac{\sqrt{a}}{\sqrt{b}}$
- To rationalise the denominator means to remove the surd from the denominator of a fraction.
- To rationalise $\frac{a}{\sqrt{b}}$ you multiply the numerator and denominator by the surd $\sqrt{b}$
- To rationalise $\frac{a}{b+\sqrt{c}}$ you multiply the numerator and denominator by $b-\sqrt{c}$

## Examples

Example 1 Simplify $\sqrt{50}$

| $\sqrt{50}=\sqrt{25 \times 2}$ | 1 <br> Choose two numbers that are <br> factors of 50. One of the factors <br> must be a square number <br> $=\sqrt{25} \times \sqrt{2}$ <br> $=5 \times \sqrt{2}$ <br> $=5 \sqrt{2}$ |
| :--- | :--- |
| $\mathbf{2}$Use the rule $\sqrt{a b}=\sqrt{a} \times \sqrt{b}$ |  |
| $\mathbf{3}$Use $\sqrt{25}=5$ |  |

Example 2 Simplify $\sqrt{147}-2 \sqrt{12}$

$$
\begin{aligned}
& \sqrt{147}-2 \sqrt{12} \\

& =7 \times \sqrt{3}-2 \times 2 \times \sqrt{3} \\
& =7 \sqrt{3}-4 \sqrt{3}
\end{aligned}
$$

1 Simplify $\sqrt{147}$ and $2 \sqrt{12}$. Choose two numbers that are factors of 147 and two numbers that are factors of 12. One of each pair of factors must be a square number
2 Use the rule $\sqrt{a b}=\sqrt{a} \times \sqrt{b}$

& =\frac{1 \times \sqrt{3}}{\sqrt{9}} \\
& =\frac{\sqrt{3}}{3}
\end{aligned}
$$

1 Multiply the numerator and denominator by $\sqrt{3}$

2 Use $\sqrt{9}=3$

Example 5 Rationalise and simplify $\frac{\sqrt{2}}{\sqrt{12}}$

$$
\begin{aligned}
\frac{\sqrt{2}}{\sqrt{12}} & =\frac{\sqrt{2}}{\sqrt{12}} \times \frac{\sqrt{12}}{\sqrt{12}} \\
& =\frac{\sqrt{2} \times \sqrt{4 \times 3}}{12} \\
& =\frac{2 \sqrt{2} \sqrt{3}}{12} \\
& =\frac{\sqrt{2} \sqrt{3}}{6}
\end{aligned}
$$

1 Multiply the numerator and denominator by $\sqrt{12}$

2 Simplify $\sqrt{12}$ in the numerator. Choose two numbers that are factors of 12 . One of the factors must be a square number

3 Use the rule $\sqrt{a b}=\sqrt{a} \times \sqrt{b}$
4 Use $\sqrt{4}=2$

$\frac{2}{12}$ simplifies to $\frac{1}{6}$

Example 6 Rationalise and simplify $\frac{3}{2+\sqrt{5}}$

## Factorising expressions

## A LEVEL LINKS

Scheme of work: 1 b . Quadratic functions - factorising, solving, graphs and the discriminants

## Key points

- Factorising an expression is the opposite of expanding the brackets.
- A quadratic expression is in the form $a x^{2}+b x+c$, where $a \neq 0$.
- To factorise a quadratic equation find two numbers whose sum is $b$ and whose product is $a c$.
- An expression in the form $x^{2}-y^{2}$ is called the difference of two squares. It factorises to $(x-y)(x+y)$.

## Examples

Example 1 Factorise $15 x^{2} y^{3}+9 x^{4} y$
$15 x^{2} y^{3}+9 x^{4} y=3 x^{2} y\left(5 y^{2}+3 x^{2}\right)$
The highest common factor is $3 x^{2} y$. So take $3 x^{2} y$ outside the brackets and then divide each term by $3 x^{2} y$ to find the terms in the brackets

Example 2 Factorise $4 x^{2}-25 y^{2}$

$$
4 x^{2}-25 y^{2}=(2 x+5 y)(2 x-5 y)
$$

This is the difference of two squares as the two terms can be written as $(2 x)^{2}$ and $(5 y)^{2}$

Example 3 Factorise $x^{2}+3 x-10$

$$
\begin{aligned}
& b=3, a c=-10 \\
& \begin{aligned}
\text { So } x^{2}+3 x-10 & =x^{2}+5 x-2 x-10 \\
& =x(x+5)-2(x+5) \\
& =(x+5)(x-2)
\end{aligned}
\end{aligned}
$$

1 Work out the two factors of $a c=-10$ which add to give $b=3$ (5 and -2)
2 Rewrite the $b$ term (3x) using these two factors
3 Factorise the first two terms and the last two terms
$4(x+5)$ is a factor of both terms

Example 4 Factorise $6 x^{2}-11 x-10$

$$
\begin{aligned}
& b=-11, a c=-60 \\
& \text { So } \\
& \begin{aligned}
6 x^{2}-11 x-10 & =6 x^{2}-15 x+4 x-10 \\
& =3 x(2 x-5)+2(2 x-5) \\
& =(2 x-5)(3 x+2)
\end{aligned}
\end{aligned}
$$

1 Work out the two factors of $a c=-60$ which add to give $b=-11$ (-15 and 4)
2 Rewrite the $b$ term ( $-11 x$ ) using these two factors
3 Factorise the first two terms and the last two terms
$4(2 x-5)$ is a factor of both terms

Example $5 \quad$ Simplify $\frac{x^{2}-4 x-21}{2 x^{2}+9 x+9}$
$\frac{x^{2}-4 x-21}{2 x^{2}+9 x+9}$

For the numerator:
$b=-4, a c=-21$
So

$$
\begin{aligned}
x^{2}-4 x-21 & =x^{2}-7 x+3 x-21 \\
& =x(x-7)+3(x-7) \\
& =(x-7)(x+3)
\end{aligned}
$$

For the denominator:
$b=9, a c=18$
So
$2 x^{2}+9 x+9=2 x^{2}+6 x+3 x+9$

$$
=2 x(x+3)+3(x+3)
$$

$$
=(x+3)(2 x+3)
$$

So

$$
\begin{aligned}
\frac{x^{2}-4 x-21}{2 x^{2}+9 x+9} & =\frac{(x-7)(x+3)}{(x+3)(2 x+3)} \\
& =\frac{x-7}{2 x+3}
\end{aligned}
$$

1 Factorise the numerator and the denominator

2 Work out the two factors of $a c=-21$ which add to give $b=-4$ ( -7 and 3 )

3 Rewrite the $b$ term ( $-4 x$ ) using these two factors
4 Factorise the first two terms and the last two terms
$5(x-7)$ is a factor of both terms
6 Work out the two factors of $a c=18$ which add to give $b=9$ (6 and 3)

7 Rewrite the $b$ term ( $9 x$ ) using these two factors
8 Factorise the first two terms and the last two terms
$9(x+3)$ is a factor of both terms
$10(x+3)$ is a factor of both the numerator and denominator so cancels out as a value divided by itself is 1

## Practice

1 Factorise.
a $\quad 6 x^{4} y^{3}-10 x^{3} y^{4}$
b $\quad 21 a^{3} b^{5}+35 a^{5} b^{2}$
c $25 x^{2} y^{2}-10 x^{3} y^{2}+15 x^{2} y^{3}$

2 Factorise

## Hint

Take the highest common factor outside the bracket.
a $\quad x^{2}+7 x+12$
b $\quad x^{2}+5 x-14$
c $x^{2}-11 x+30$
d $x^{2}-5 x-24$
e $\quad x^{2}-7 x-18$
g $\quad x^{2}-3 x-40$
f $\quad x^{2}+x-20$
h $\quad x^{2}+3 x-28$

3 Factorise
a $36 x^{2}-49 y^{2}$
b $4 x^{2}-81 y^{2}$

4 Factorise

b $6 x^{2}+17 x+5$
c $\quad 2 x^{2}+7 x+3$
d $9 x^{2}-15 x+4$
e $10 x^{2}+21 x+9$
f $\quad 12 x^{2}-38 x+20$

b $\frac{x^{2}+3 x}{x^{2}+2 x-3}$
c $\frac{x^{2}-2 x-8}{x^{2}-4 x}$
d $\frac{x^{2}-5 x}{x^{2}-25}$
e $\frac{x^{2}-x-12}{x^{2}-4 x}$
f $\frac{2 x^{2}+14 x}{2 x^{2}+4 x-70}$

6 Simplify
a $\frac{9 x^{2}-16}{3 x^{2}+17 x-28}$
b $\frac{2 x^{2}-7 x-15}{3 x^{2}-17 x+10}$
c $\frac{4-25 x^{2}}{10 x^{2}-11 x-6}$
d $\frac{6 x^{2}-x-1}{2 x^{2}+7 x-4}$

## Extend

7 Simplify $\sqrt{x^{2}+10 x+25}$

8 Simplify $\frac{(x+2)^{2}+3(x+2)^{2}}{x^{2}-4}$

## Completing the square

A LEVEL LINKS
Scheme of work: 1 b . Quadratic functions - factorising, solving, graphs and the discriminants

## Key points

- Completing the square for a quadratic rearranges $a x^{2}+b x+c$ into the form $p(x+q)^{2}+r$
- If $a \neq 1$, then factorise using $a$ as a common factor.

## Examples

Example 1 Complete the square for the quadratic expression $x^{2}+6 x-2$

$$
\begin{aligned}
& x^{2}+6 x-2 \\
& =(x+3)^{2}-9-2 \\
& =(x+3)^{2}-11
\end{aligned}
$$

1 Write $x^{2}+b x+c$ in the form
$\left(x+\frac{b}{2}\right)^{2}-\left(\frac{b}{2}\right)^{2}+c$
2 Simplify

Example 2 Write $2 x^{2}-5 x+1$ in the form $p(x+q)^{2}+r$

$$
\begin{aligned}
& 2 x^{2}-5 x+1 \\
& =2\left(x^{2}-\frac{5}{2} x\right)+1 \\
& =2\left[\left(x-\frac{5}{4}\right)^{2}-\left(\frac{5}{4}\right)^{2}\right]+1 \\
& =2\left(x-\frac{5}{4}\right)^{2}-\frac{25}{8}+1 \\
& =2\left(x-\frac{5}{4}\right)^{2}-\frac{17}{8}
\end{aligned}
$$

1 Before completing the square write $a x^{2}+b x+c$ in the form
$a\left(x^{2}+\frac{b}{a} x\right)+c$
2 Now complete the square by writing $x^{2}-\frac{5}{2} x$ in the form $\left(x+\frac{b}{2}\right)^{2}-\left(\frac{b}{2}\right)^{2}$

3 Expand the square brackets - don't forget to multiply $\left(\frac{5}{4}\right)^{2}$ by the factor of 2

4 Simplify

## Practice

1 Write the following quadratic expressions in the form $(x+p)^{2}+q$
a $\quad x^{2}+4 x+3$

e $\quad x^{2}-2 x+7$
f $\quad x^{2}+3 x-2$

2 Write the following quadratic expressions in the form $p(x+q)^{2}+r$
a $2 x^{2}-8 x-16$
b $4 x^{2}-8 x-16$
c $3 x^{2}+12 x-9$
d $2 x^{2}+6 x-8$

3 Complete the square.
a $\quad 2 x^{2}+3 x+6$
b $3 x^{2}-2 x$

# Solving quadratic equations by <br> factorisation 

## A LEVEL LINKS

Scheme of work: 1b. Quadratic functions - factorising, solving, graphs and the discriminants

## Key points

- A quadratic equation is an equation in the form $a x^{2}+b x+c=0$ where $a \neq 0$.
- To factorise a quadratic equation find two numbers whose sum is $b$ and whose products is ac.
- When the product of two numbers is 0 , then at least one of the numbers must be 0 .
- If a quadratic can be solved it will have two solutions (these may be equal).

## Examples

Example 1 Solve $5 x^{2}=15 x$

$$
\begin{aligned}
& 5 x^{2}=15 x \\
& 5 x^{2}-15 x=0 \\
& 5 x(x-3)=0 \\
& \text { So } 5 x=0 \text { or }(x-3)=0 \\
& \text { Therefore } x=0 \text { or } x=3
\end{aligned}
$$

1 Rearrange the equation so that all of the terms are on one side of the equation and it is equal to zero. Do not divide both sides by $x$ as this would lose the solution $x=0$.
2 Factorise the quadratic equation. $5 x$ is a common factor.
3 When two values multiply to make zero, at least one of the values must be zero.
4 Solve these two equations.

Example 2 Solve $x^{2}+7 x+12=0$
$x^{2}+7 x+12=0$
$b=7, a c=12$
$x^{2}+4 x+3 x+12=0$
$x(x+4)+3(x+4)=0$
$(x+4)(x+3)=0$
So $(x+4)=0$ or $(x+3)=0$
Therefore $x=-4$ or $x=-3$

1 Factorise the quadratic equation.
Work out the two factors of $a c=12$
which add to give you $b=7$.
(4 and 3)
2 Rewrite the $b$ term (7x) using these two factors.
3 Factorise the first two terms and the last two terms.
$4(x+4)$ is a factor of both terms.
5 When two values multiply to make zero, at least one of the values must be zero.
6 Solve these two equations.

Example 3 Solve $9 x^{2}-16=0$

$$
\begin{aligned}
& 9 x^{2}-16=0 \\
& (3 x+4)(3 x-4)=0 \\
& \text { So }(3 x+4)=0 \text { or }(3 x-4)=0 \\
& x=-\frac{4}{3} \text { or } x=\frac{4}{3}
\end{aligned}
$$

1 Factorise the quadratic equation. This is the difference of two squares as the two terms are $(3 x)^{2}$ and $(4)^{2}$.
2 When two values multiply to make zero, at least one of the values must be zero.
3 Solve these two equations.

Example 4 Solve $2 x^{2}-5 x-12=0$
$b=-5, a c=-24$

So $2 x^{2}-8 x+3 x-12=0$
$2 x(x-4)+3(x-4)=0$
$(x-4)(2 x+3)=0$
So $(x-4)=0$ or $(2 x+3)=0$
$x=4$ or $x=-\frac{3}{2}$

1 Factorise the quadratic equation.
Work out the two factors of $a c=-24$ which add to give you $b=-5$.
( -8 and 3)
2 Rewrite the $b$ term ( $-5 x$ ) using these two factors.
3 Factorise the first two terms and the last two terms.
$4(x-4)$ is a factor of both terms.
5 When two values multiply to make zero, at least one of the values must be zero.
6 Solve these two equations.

## Practice

a $\quad 6 x^{2}+4 x=0$
b $28 x^{2}-21 x=0$

## Key points

- Completing the square lets you write a quadratic equation in the form $p(x+q)^{2}+r=0$.

## Examples

Example 5 Solve $x^{2}+6 x+4=0$. Give your solutions in surd form.

$$
\begin{aligned}
& x^{2}+6 x+4=0 \\
& (x+3)^{2}-9+4=0 \\
& (x+3)^{2}-5=0 \\
& (x+3)^{2}=5 \\
& x+3= \pm \sqrt{5} \\
& x= \pm \sqrt{5}-3 \\
& \text { So } x=-\sqrt{5}-3 \text { or } x=\sqrt{5}-3
\end{aligned}
$$

1 Write $x^{2}+b x+c=0$ in the form $\left(x+\frac{b}{2}\right)^{2}-\left(\frac{b}{2}\right)^{2}+c=0$
2 Simplify.
3 Rearrange the equation to work out $x$. First, add 5 to both sides.
4 Square root both sides.
Remember that the square root of a value gives two answers.
5 Subtract 3 from both sides to solve the equation.
6 Write down both solutions.

Example 6 Solve $2 x^{2}-7 x+4=0$. Give your solutions in surd form.

$$
\begin{aligned}
& 2 x^{2}-7 x+4=0 \\
& 2\left(x^{2}-\frac{7}{2} x\right)+4=0 \\
& 2\left[\left(x-\frac{7}{4}\right)^{2}-\left(\frac{7}{4}\right)^{2}\right]+4=0 \\
& 2\left(x-\frac{7}{4}\right)^{2}-\frac{49}{8}+4=0 \\
& 2\left(x-\frac{7}{4}\right)^{2}-\frac{17}{8}=0
\end{aligned}
$$

1 Before completing the square write $a x^{2}+b x+c$ in the form
$a\left(x^{2}+\frac{b}{a} x\right)+c$
2 Now complete the square by writing $x^{2}-\frac{7}{2} x$ in the form $\left(x+\frac{b}{2 a}\right)^{2}-\left(\frac{b}{2 a}\right)^{2}$

3 Expand the square brackets.

4 Simplify.
$2\left(x-\frac{7}{4}\right)^{2}=\frac{17}{8}$
$\left(x-\frac{7}{4}\right)^{2}=\frac{17}{16}$
$x-\frac{7}{4}= \pm \frac{\sqrt{17}}{4}$
$x= \pm \frac{\sqrt{17}}{4}+\frac{7}{4}$
So $x=\frac{7}{4}-\frac{\sqrt{17}}{4}$ or $x=\frac{7}{4}+\frac{\sqrt{17}}{4}$
(continued on next page)
5 Rearrange the equation to work out $x$. First, add $\frac{17}{8}$ to both sides.

6 Divide both sides by 2.

7 Square root both sides. Remember that the square root of a value gives two answers.
8 Add $\frac{7}{4}$ to both sides.
9 Write down both the solutions.

## Solving quadratic equations by using the formula

## A LEVEL LINKS

Scheme of work: 1b. Quadratic functions - factorising, solving, graphs and the discriminants

## Key points

- Any quadratic equation of the form $a x^{2}+b x+c=0$ can be solved using the formula
$x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}$
- If $b^{2}-4 a c$ is negative then the quadratic equation does not have any real solutions.
- It is useful to write down the formula before substituting the values for $a, b$ and $c$.

## Examples

Example 7 Solve $x^{2}+6 x+4=0$. Give your solutions in surd form.

$$
\begin{aligned}
& a=1, b=6, c=4 \\
& x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a} \\
& x=\frac{-6 \pm \sqrt{6^{2}-4(1)(4)}}{2(1)} \\
& x=\frac{-6 \pm \sqrt{20}}{2} \\
& x=\frac{-6 \pm 2 \sqrt{5}}{2} \\
& x=-3 \pm \sqrt{5} \\
& \text { So } x=-3-\sqrt{5} \text { or } x=\sqrt{5}-3
\end{aligned}
$$

1 Identify $a, b$ and $c$ and write down the formula.
Remember that $-b \pm \sqrt{b^{2}-4 a c}$ is all over $2 a$, not just part of it.

2 Substitute $a=1, b=6, c=4$ into the formula.

3 Simplify. The denominator is 2 , but this is only because $a=1$. The denominator will not always be 2 .

4 Simplify $\sqrt{20}$.
$\sqrt{20}=\sqrt{4 \times 5}=\sqrt{4} \times \sqrt{5}=2 \sqrt{5}$
5 Simplify by dividing numerator and denominator by 2 .
6 Write down both the solutions.

Example 8 Solve $3 x^{2}-7 x-2=0$. Give your solutions in surd form.

$$
\begin{aligned}
& a=3, b=-7, c=-2 \\
& x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a} \\
& x=\frac{-(-7) \pm \sqrt{(-7)^{2}-4(3)(-2)}}{2(3)} \\
& x=\frac{7 \pm \sqrt{73}}{6} \\
& \text { So } x=\frac{7-\sqrt{73}}{6} \text { or } x=\frac{7+\sqrt{73}}{6}
\end{aligned}
$$

1 Identify $a, b$ and $c$, making sure you get the signs right and write down the formula.
Remember that $-b \pm \sqrt{b^{2}-4 a c}$ is all over $2 a$, not just part of it.

2 Substitute $a=3, b=-7, c=-2$ into the formula.

3 Simplify. The denominator is 6 when $a=3$. A common mistake is to always write a denominator of 2 .

## Sketching quadratic graphs

## A LEVEL LINKS

Scheme of work: 1b. Quadratic functions - factorising, solving, graphs and the discriminants

## Key points

- The graph of the quadratic function $y=a x^{2}+b x+c$, where $a \neq 0$, is a curve called a parabola.
- Parabolas have a line of symmetry and
 a shape as shown.
- To sketch the graph of a function, find the points where the graph intersects the axes.
- To find where the curve intersects the $y$-axis substitute $x=0$ into the function.
- To find where the curve intersects the $x$-axis substitute $y=0$ into the function.
- At the turning points of a graph the gradient of the curve is 0 and any tangents to the curve at these points are horizontal.
- To find the coordinates of the maximum or minimum point (turning points) of a quadratic curve (parabola) you can use the completed square form of the function.

## Examples

Example 1 Sketch the graph of $y=x^{2}$.

| $O$ | The graph of $y=x^{2}$ is a parabola. <br> When $x=0, y=0$. <br> $a=1$ which is greater <br> than zero, so the graph <br> has the shape: |

Example 2 Sketch the graph of $y=x^{2}-x-6$.

When $x=0, y=0^{2}-0-6=-6$
So the graph intersects the $y$-axis at (0,-6)
When $y=0, x^{2}-x-6=0$
$(x+2)(x-3)=0$
$x=-2$ or $x=3$
So,
the graph intersects the $x$-axis at $(-2,0)$ and ( 3,0 )

1 Find where the graph intersects the $y$-axis by substituting $x=0$.

2 Find where the graph intersects the $x$-axis by substituting $y=0$.
3 Solve the equation by factorising.
4 Solve $(x+2)=0$ and $(x-3)=0$.

## Solving linear simultaneous equations using the elimination method

## A LEVEL LINKS

Scheme of work: 1c. Equations - quadratic/linear simultaneous

## Key points

- Two equations are simultaneous when they are both true at the same time.
- Solving simultaneous linear equations in two unknowns involves finding the value of each unknown which works for both equations.
- Make sure that the coefficient of one of the unknowns is the same in both equations.
- Eliminate this equal unknown by either subtracting or adding the two equations.

## Examples

Example 1 Solve the simultaneous equations $3 x+y=5$ and $x+y=1$

| $\begin{array}{r} 3 x+y=5 \\ -\quad x+y=1 \\ \hline \end{array}$ | 1 Subtract the second equation from the first equation to eliminate the $y$ |
| :---: | :---: |
| $2 x=4$ | term. |
| So $x=2$ |  |
| $\begin{aligned} \text { Using } x+y & =1 \\ 2+y & =1 \end{aligned}$ | To find the value of $y$, substitute $x=2$ into one of the original equations. |
|  |  |
| So $y=-1$ |  |
| Check: | 3 Substitute the values of $x$ and $y$ into |
| equation 1: $3 \times 2+(-1)=5$ YES | both equations to check your |
| equation 2: $2+(-1)=1 \quad$ YES | answers. |

Example 2 Solve $x+2 y=13$ and $5 x-2 y=5$ simultaneously.

| $x+2 y=13$ |
| ---: |
| $+\quad 5 x-2 y=5$ |
| $6 x=18$ |

So $x=3$

Using $x+2 y=13$
$3+2 y=13$
So $y=5$
Check:
equation 1: $3+2 \times 5=13 \quad$ YES
equation $2: 5 \times 3-2 \times 5=5$ YES

1 Add the two equations together to eliminate the $y$ term.

2 To find the value of $y$, substitute $x=3$ into one of the original equations.

3 Substitute the values of $x$ and $y$ into both equations to check your answers.

Example 3 Solve $2 x+3 y=2$ and $5 x+4 y=12$ simultaneously.
$(2 x+3 y=2) \times 4 \rightarrow \quad 8 x+12 y=8$
$(5 x+4 y=12) \times 3 \rightarrow \frac{15 x+12 y=36}{7 x}=28$

So $x=4$

Using $2 x+3 y=2$

$$
2 \times 4+3 y=2
$$

So $y=-2$
Check:
equation 1: $2 \times 4+3 \times(-2)=2 \quad$ YES equation 2: $5 \times 4+4 \times(-2)=12$ YES

1 Multiply the first equation by 4 and the second equation by 3 to make the coefficient of $y$ the same for both equations. Then subtract the first equation from the second equation to eliminate the $y$ term.

2 To find the value of $y$, substitute $x=4$ into one of the original equations.

3 Substitute the values of $x$ and $y$ into both equations to check your answers.

## Sketching cubic and reciprocal graphs

## A LEVEL LINKS

Scheme of work: 1 e . Graphs - cubic, quartic and reciprocal

## Key points

- The graph of a cubic function, which can be written in the form $y=a x^{3}+b x^{2}+c x+d$, where $a \neq 0$, has one of the shapes shown here.

special case: $a=1$

special case: $a=-1$

- To sketch the graph of a function, find the points where the graph intersects the axes.
- To find where the curve intersects the $y$-axis substitute $x=0$ into the function.
- To find where the curve intersects the $x$-axis substitute $y=0$ into the function.
- Where appropriate, mark and label the asymptotes on the graph.
- Asymptotes are lines (usually horizontal or vertical) which the curve gets closer to but never touches or crosses. Asymptotes usually occur with reciprocal functions. For example, the asymptotes for the graph of $y=\frac{a}{x}$ are the two axes (the lines $y=0$ and $x=0$ ).
- At the turning points of a graph the gradient of the curve is 0 and any tangents to the curve at these points are horizontal.
- A double root is when two of the solutions are equal. For example $(x-3)^{2}(x+2)$ has a double root at $x=3$.
- When there is a double root, this is one of the turning points of a cubic function.

## Examples

Example 1 Sketch the graph of $y=(x-3)(x-1)(x+2)$
To sketch a cubic curve find intersects with both axes and use the key points above for the correct shape.

When $x=0, y=(0-3)(0-1)(0+2)$

$$
=(-3) \times(-1) \times 2=6
$$

The graph intersects the $y$-axis at $(0,6)$
When $y=0,(x-3)(x-1)(x+2)=0$
So $x=3, x=1$ or $x=-2$
The graph intersects the $x$-axis at $(-2,0),(1,0)$ and $(3,0)$

1 Find where the graph intersects the axes by substituting $x=0$ and $y=0$. Make sure you get the coordinates the right way around, $(x, y)$.
2 Solve the equation by solving $x-3=0, x-1=0$ and $x+2=0$

3 Sketch the graph.
$a=1>0$ so the graph has the shape:

Example 2 Sketch the graph of $y=(x+2)^{2}(x-1)$
To sketch a cubic curve find intersects with both axes and use the key points above for the correct shape.

$$
\begin{gathered}
\text { When } x=0, y=(0+2)^{2}(0-1) \\
=2^{2} \times(-1)=-4
\end{gathered}
$$

The graph intersects the $y$-axis at $(0,-4)$
When $y=0,(x+2)^{2}(x-1)=0$
So $x=-2$ or $x=1$
$(-2,0)$ is a turning point as $x=-2$ is a double root.
The graph crosses the $x$-axis at $(1,0)$

1 Find where the graph intersects the axes by substituting $x=0$ and $y=0$.

2 Solve the equation by solving $x+2=0$ and $x-1=0$
$3 a=1>0$ so the graph has the shape:

## Practice

C $y=x^{3}+3 x^{2}$
D $y=1-3 x^{2}-x^{3}$
E $y=x^{3}-3 x^{2}-1$
F $\quad x+y=5$

Here are six graphs.
i

ii

iii

iv

v

vi

a Match each graph to its equation.
b Copy the graphs ii, iv and vi and draw the tangent and normal each at point $P$.

Sketch the following graphs
$2 y=2 x^{3}$
$3 y=x(x-2)(x+2)$
$4 \quad y=(x+1)(x+4)(x-3)$
$5 \quad y=(x+1)(x-2)(1-x)$
$6 \quad y=(x-3)^{2}(x+1)$
$8 y=\frac{3}{x}$
Hint: Look at the shape of $y=\frac{a}{x}$ in the second key point.
